6. Data and Performance Analysis
7. Case Studies and Examples
8. Discussion and Future Directions
9. Conclusion

Executive Summary

This report provides an in-depth survey of the latest AI-driven tools for **mapping scientific literature**. Modern research generates an immense volume of publications, making manual literature reviews increasingly difficult. A new class of *literature mapping tools* has emerged, leveraging bibliometric data and AI methods to visualize and organize vast bodies of research. Tools like **Litmaps**, **ResearchRabbit**, and **Connected Papers** create interactive citation networks and concept maps, helping researchers "see" how papers interrelate. Other platforms, such as **Elicit**, use large language models (LLMs) to automate search, summarization, and data extraction from literature. We examine the features, strengths, and limitations of these platforms, citing user studies and expert reviews. For example, **ResearchRabbit**'s developers claim a database of *"hundreds of millions of academic articles"* (second only to Google Scholar (pmc.ncbi.nlm.nih.gov)), while librarians note that ResearchRabbit builds *"dynamic, interactive citation and co-author graphs"* (intranet.abertay.ac.uk). We evaluate evidence on performance (e.g. sensitivity/precision of AI search (labs.sciety.org)), discuss case studies (researchers' experiences with these tools), and explore their roles in systematic reviews, knowledge discovery, and teaching. Finally, we consider future directions (better integration of full-text data, reproducibility concerns, and the role of generative AI in literature mapping) and implications for scholarly research workflow.

Introduction

Conducting comprehensive literature reviews is a cornerstone of scientific research. Traditionally, scholars relied on keyword searches in databases (e.g. Web of Science, Scopus, or Google Scholar) and manual reading to discover relevant prior work (intranet.abertay.ac.uk) (pmc.ncbi.nlm.nih.gov). However, the explosion of published research has made this process laborious. Fortunately, advances in open citation data and AI have given rise to **literature mapping tools** – software platforms that use algorithms to visualize the structure of a research field. These tools go beyond simple search by creating *interactive graphs* where nodes represent papers and edges represent citations, co-citations, or topical similarity. A recent overview by academic librarians explains that *"literature mapping tools help you explore how research papers are connected —*

visually and conceptually" (intranet.abertay.ac.uk). For example, ResearchRabbit and Connected Papers generate citation networks around key "seed" papers, while Litmaps offers timeline-based maps that track research developments over time (intranet.abertay.ac.uk).

In parallel, AI-driven research assistants like **Elicit** have emerged, leveraging large language models (LLMs) to automate parts of the review process. These tools can answer research questions, synthesize findings, and suggest new references. Elicit, for example, uses semantic similarity (similar to GPT-3.5) to find relevant papers and can generate summary "custom reports" on a given topic (bmcmedresmethodol.biomedcentral.com). While not strictly a "mapping" tool, Elicit exemplifies how generative AI is reshaping literature discovery and review, complementing visual mapping approaches.

This report surveys these new tools and situates them in context. We first review the landscape of AI-based literature mapping platforms, then examine AI search and summarization assistants, followed by data and user-experience studies. Throughout, we use empirical data and published analyses to compare their performance and use cases. We include tables summarizing features (see below) and case vignettes illustrating real-world use. Finally, we discuss implications for future research workflows.

Background: Literature Mapping and AI in Research

The idea of *mapping scientific literature* has roots in bibliometrics and scientometrics. Early scientists like Eugene Garfield and Henry Small pioneered citation indexing and co-citation analysis to understand research trends. Tools like **CiteSpace** and **VOSviewer** from the 2000s perform classic network analysis of citations or keywords. What's new today is the integration of AI techniques and modern web-based interfaces. Contemporary mapping tools draw on large open datasets (Microsoft Academic Graph, Semantic Scholar, Crossref, OpenAlex) and apply graph algorithms and machine learning for recommendations.

As Chaomei Chen (a leading expert on science mapping) notes, visual scientometric techniques can "improve the timeliness and accessibility" of literature reviews (www.researchgate.net). For example, visualization can help a researcher *"snorkel and deep-dive"* into a topic by showing citation paths, co-author networks, or clusters of related work. These visual maps serve as analytical aids: highlighting seminal papers, uncovering interdisciplinary links, and revealing gaps in existing knowledge.

Literature mapping tools primarily explore connections between papers; AI research also includes assistants such as ChatGPT. Some services combine literature mapping and generative AI research assistance (Abertay University guide). In many cases they rely on large language models (LLMs) indirectly, for example to compute document embeddings or semantic similarity. For example, Connected Papers uses co-citation and bibliographic coupling (techniques akin to latent semantic analysis) to position papers in a force-directed graph (aarontay.medium.com) (www.researchgate.net).

The emergence of these tools is timely. Traditional reviews can take months or even years. Users report dramatic improvements: one student wrote "what used to take me three weeks manually now takes three to four days" when using AI research tools (techpoint.africa). Librarians emphasize that **search integration** is key: tools that connect to PubMed, arXiv, or Crossref save researchers from slogging through dozens of legacy databases (techpoint.africa) (pmc.ncbi.nlm.nih.gov). Indeed, a recent survey of AI-for-research tools notes that *"integrations with major academic databases such as PubMed, Google Scholar, and Web of*

Science are more important than features" (techpoint.africa). This means tools like ResearchRabbit (which leverages PubMed and Semantic Scholar searches (pmc.ncbi.nlm.nih.gov)) and Litmaps (which integrates Crossref and OpenAlex (docs.litmaps.com)) are particularly powerful. Table 1 (below) compares leading literature-mapping tools side by side, summarizing their purpose, data coverage, and key features.

Tool	Best for / Focus	Key Features	Data Sources & Coverage	Freemium Model (Key Limits)
ResearchRabbit	**Exploration from seed papers**	Dynamic citation & co-author graphs; "flow" interface from paper-to-paper (pmc.ncbi.nlm.nih.gov). Shared collections, alerting on new papers.	Database of 310+ million research articles (ResearchRabbit).	Free tier includes shared collections for collaborators (ResearchRabbit Free Tier); checked 20 October 2026.
Litmaps	**Timeline mapping of research**	Timeline-based citation maps; overlays showing when and how a topic evolves. Custom annotations, tagging, and sharing (intranet.abertay.ac.uk) (docs.litmaps.com). Alerting on new publications.	Aggregates 270M+ research articles with open metadata via Crossref, Semantic Scholar, and OpenAlex (including metadata from PubMed, arXiv, MAG, Scopus, etc.) (docs.litmaps.com). Works best on STEM literature with open metadata.	Freemium: Limited seeds/maps on free plan. Pro ($8–10/mo) allows unlimited maps, alerts, exports (intranet.abertay.ac.uk). (Includes both open-access and closed-access articles; see database coverage.)
Connected Papers	**One-shot seed-based mapping**	Graph of papers related to one seed; uses co-citation + bibliographic coupling for *semantic similarity* instead of direct citations (aarontay.medium.com) (www.researchgate.net). Node size = citations, colored by year (aarontay.medium.com). Allows 'prior works'/'derivative works' view.	Data drawn from Semantic Scholar (Google Scholar, WoS, MAG metadata via Semantic Scholar API) (academiainsider.com). Map generation covers fields beyond biomedicine.	Freemium: five graphs per month with all features included; paid plans remove the graph limit (Connected Papers pricing; checked 20 October 2026). (Graph lines show similarity, not necessarily citation links (aarontay.medium.com).)
Inciteful	**Network pathfinding / interdisciplinary**	Citation-path analysis: identifies *"bridge"* papers linking fields. Generates multiple lists: Similar papers (Adamic/Adar), Most Important (PageRank), Recent Authors, etc (aarontay.medium.com). Allows iterative seed addition and Boolean/SQL filters (aarontay.medium.com).	Depends on open scholarly data projects; see its Data Sources documentation. Supports bulk import of seed papers via BibTeX/RIS.	Free (web app); no limits noted for pathfinding. (No clear paid tier). Some documentation for SQL-based customization (aarontay.medium.com).

Table 1: Comparison of key literature mapping tools. Each of these tools creates network visualizations of papers. For example, ResearchRabbit and Connected Papers both start from one or more **seed papers** and build an interactive map of related work (aarontay.medium.com) (pmc.ncbi.nlm.nih.gov). In contrast, Litmaps focuses on showing *when* papers were published (timeline view) and allows ongoing alerting on a topic (intranet.abertay.ac.uk). Inciteful is designed for deeper analysis of citation paths between topics (intranet.abertay.ac.uk) (aarontay.medium.com).

Below we describe these and other tools in detail, including how they work, their underlying AI, and user experiences.

Literature Mapping Tools

ResearchRabbit

Overview: ResearchRabbit is a web-based “research discovery engine” launched in 2021 by a small Seattle team (pmc.ncbi.nlm.nih.gov). It is often described as “**Spotify for papers**” (www.researchgate.net). The user experience is organized around **collections** of papers. One starts by adding one or more seed papers (by DOI, title, or BibTeX). ResearchRabbit then continuously recommends more papers, akin to how a music app suggests songs when you add to a playlist (www.researchgate.net). The platform visualizes these suggestions in an interactive **column-based interface**: each paper can be expanded into “All References”, “All Citations”, or “Similar Work” views. New columns open to the right, forming a treelike path as the user drills down. This supports an “unstructured search” workflow (pmc.ncbi.nlm.nih.gov): for example, you can click “All citations” on a paper and see all its incoming citations, then click on a returned paper’s references, and so on (pmc.ncbi.nlm.nih.gov). The default visualization is a simple network showing how the current collection relates by citations (medium.com) (green nodes are already in your library, blue are external; authors appear as red nodes (pmc.ncbi.nlm.nih.gov)). The interface is designed so researchers *“never miss a thing”*, with one-click network expansions (pmc.ncbi.nlm.nih.gov) (medium.com).

Data Sources: ResearchRabbit originally relied on the Microsoft Academic Graph (MAG) for citation data (medium.com) (intranet.abertay.ac.uk). MAG was a comprehensive open academic database, but it was discontinued in 2021. ResearchRabbit now pulls from Semantic Scholar and PubMed search queries for coverage (pmc.ncbi.nlm.nih.gov). According to Cole and Boutet (2023), ResearchRabbit’s own “unique database of *‘hundreds of millions of academic articles’ is second in size only to Google Scholar*” (pmc.ncbi.nlm.nih.gov). In practice, users have access to PubMed data (for biomedical literature) and Semantic Scholar’s corpus (multi-disciplinary, including computer science, etc.) (pmc.ncbi.nlm.nih.gov). However, Librarian guides warn that coverage depends on open datasets: paywalled content from publishers may be missing (intranet.abertay.ac.uk). Notably, ResearchRabbit supports key science fields well, but is weaker in humanities or law, and has almost no book coverage (intranet.abertay.ac.uk).

Features: The standout feature of ResearchRabbit is its **continuous visual trail**. As a user adds more papers to their collection, ResearchRabbit continuously updates its recommendations and the network map (www.researchgate.net). The map highlights co-authorship networks (red nodes are authors) and citation distance from the collection (pmc.ncbi.nlm.nih.gov). It shows both spatial networks and timeline charts. For example, the “Timeline view” arranges collected papers along a time axis (pmc.ncbi.nlm.nih.gov), while the “Network view” plots a citation graph to reveal clusters of related work. Researchers can filter results, export to reference managers, and join shared collections with peers (pmc.ncbi.nlm.nih.gov).

User Experience and Limitations: According to Cole and Boutet (2023), ResearchRabbit is accessed via a browser and requires no additional software (pmc.ncbi.nlm.nih.gov). It is keyboard-navigable and offers screen-reader compatibility, though the dense interface can be overwhelming. A library review notes that

ResearchRabbit's UI is *"generally navigable"* but has *"some navigation challenges"* due to many buttons and information (pmc.ncbi.nlm.nih.gov).

Aaron Tay (2021) praised ResearchRabbit's design: the column-based approach keeps the user "in the flow" and mirrors how researchers browse references (medium.com). He notes it supports easy jumping between papers and authors, and is among the first to include co-authorship networks in a review tool (medium.com). However, he warns of a learning curve and a "black box" recommendation algorithm with little transparency (medium.com). Indeed, even ResearchRabbit's own FAQ admits only that recommendations use "citation networks and some additional magic" (pmc.ncbi.nlm.nih.gov), with no detailed methodology publicly disclosed.

ResearchRabbit states that it updates its database weekly (database documentation; checked 20 October 2026). Still, systematic review practitioners are cautioned that no AI mapping tool is fully reproducible (intranet.abertay.ac.uk). The recommended practice is to document seeds and dates, since results can vary day-to-day.

Case Usage: Sharma et al. (2022) studied ResearchRabbit as a case of *"AI in libraries"*. In a literature review context, they note that ResearchRabbit "enable [s] discovery and visualizes relevant literature and scholars, creates alerts… and facilitates sharing collections" (www.researchgate.net). They report it promotes serendipitous exploration: researchers describe chasing citation links down multiple levels, losing track of how far "down the rabbit hole" they've gone, and ResearchRabbit provides a linear trail to navigate back (pmc.ncbi.nlm.nih.gov). Its *"Spotify"* recommendation approach ensured that with each new paper added, the tool suggested others, effectively expanding the researcher's horizon (www.researchgate.net). Overall, the Collnet Journal article concludes that ResearchRabbit streamlines complex literature review tasks and visualizes the "literature forest" efficiently (www.researchgate.net).

Litmaps

Overview: Litmaps (pronounced "lit-maps") bills itself as a *literature review assistant* that helps researchers build **"litmaps"** – visual graphs of papers centered on one or more seed publications. Its distinctive twist is the emphasis on **timeline visualization**. A litmap shows selected papers positioned by their publication date, effectively turning the citation graph into a temporal map (intranet.abertay.ac.uk). Users begin by entering a key paper or topic; Litmaps then finds related works and arranges them on a chronological axis. As more papers are added, the network grows, revealing when and how research ideas emerged.

Data Sources: Litmaps aggregates citations from multiple open scholarly datasets. According to their documentation, Litmaps tags over **270 million research articles** (docs.litmaps.com). It ingests metadata from Crossref, Semantic Scholar, and OpenAlex (docs.litmaps.com). These datasets in turn cover broad academic content: they include PubMed/MEDLINE, arXiv, bioRxiv, medRxiv, Web of Science, Scopus, and even Microsoft Academic Graph records (docs.litmaps.com). In practice, this means Litmaps can capture a wide swath of STEM literature. However, Litmaps relies only on *open-access metadata* (title, abstract, reference lists) (docs.litmaps.com). Closed-access publication alone does not exclude a paper: Litmaps includes both open-access and closed-access articles (Litmaps database coverage).

Features: The core feature is the **Litmap** itself. When you enter a seed paper, Litmaps generates a citation network and then "splits" it onto a timeline. Earlier works appear on the left, later works on the right, connected by citation arrows. Node size typically reflects citation count, and you can hover or click to see details

(academiainsider.com). Researchers can add multiple seeds to merge their networks. One useful capability is keyword filtering: papers can be filtered in real time by keyword, citation count, or date (academiainsider.com). Litmaps also supports tagging and organizing papers into custom collections or libraries, and exporting citations to reference managers. It provides alerts: once you've built a litmap, Litmaps can notify you of newly published papers that fit the map. For example, if a new paper cites one of your seeds or falls into a tagged topic, you get an alert. These features support an ongoing, **active** mapping of a research area, not just one-off queries (intranet.abertay.ac.uk) (academiainsider.com).

User Experience: Litmaps is web-based and fairly straightforward. A recent hands-on guide notes that you simply create a free account, enter a topic or specific paper, and Litmaps instantly displays the litmap with the chosen paper at the center (academiainsider.com). The interface is clean, with the map on screen and side panels for filters and your collection. Andy Stapleton (2024) praises its ease of use: *"the seed function is a game-changer"*, as adding one paper pulls in citing and cited works to build the network (academiainsider.com). The timeline format helps highlight key moments in the research. Users can further explore by clicking nodes to open the paper's details or citation tree.

Litmaps draws connections through citations and references. Its **Similar Text** search option instead recommends articles based on title and abstract similarity; those results can remain disconnected on the map (map connections; search algorithms).

Limitations: On the downside, Litmaps' free tier is limited: only a small number of inputs and maps are allowed without payment (intranet.abertay.ac.uk). Since it uses only open metadata, any paper not in Crossref, Semantic Scholar, or OpenAlex will be invisible. The Abertay guide warns users *"do not upload unpublished research or sensitive data"* to these tools, including Litmaps (intranet.abertay.ac.uk), as they operate on servers outside institutional firewalls.

Case Usage: Litmaps visualizes research through citation and reference connections (Create a Litmap). As a hypothetical exercise, choose a starting paper and inspect its connections; assess the relevance of each suggested paper yourself. Many conclude that for a linear topic timeline, Litmaps is ideal. As one blogger notes: *"Litmaps is an essential tool for researchers, offering an interactive way to map out the scientific literature landscape"* (academiainsider.com), and it particularly helps PhD students accelerate their reviews by detecting relevant papers they "might not discover through traditional searches" (academiainsider.com).

Connected Papers

Overview: Connected Papers is a tool that visualizes **paper relationships** starting from a single seed. It began as a weekend side project between friends (Connected Papers). Given a seed paper, Connected Papers builds a graph of papers that are conceptually related, primarily using a *semantic similarity* algorithm. The interface shows a network of typically ~25–100 nodes (papers) with the seed at the center. Unlike a strict citation map, edges in Connected Papers represent similarity, not necessarily direct citations (aarontay.medium.com). This means it uses *both* co-citation and bibliographic coupling (shared references) to infer connections (aarontay.medium.com). The end result is a clear, force-directed map where nodes near each other are highly related. Node size often encodes citation count, and node color indicates publication year (aarontay.medium.com).

Data Sources: Connected Papers relies on Semantic Scholar's database (which includes data from Google Scholar, Semantic Scholar dataset, etc.) for metadata and citations. The underlying algorithm references citations up to a certain depth. Its similarity metric uses co-citation and bibliographic coupling (Connected Papers). In 2022, Connected Papers added "multi-origin graphs" where one can add multiple seeds sequentially to refine the graph. Each time you add a paper (either the initial seed or later), the map re-generates based on new connections (aarontay.medium.com).

Features: Connected Papers' standout feature is its simple pipeline: enter one **seed paper**, and it *automatically generates* a map of relevant literature (aarontay.medium.com). The map itself is easy to interpret. In the "similar papers" view, it clusters groups of papers based on shared citations (aarontay.medium.com). Users can then click "Prior Works" to find older seminal papers commonly cited by the group, or "Derivative works" to find review articles or later works citing many of the group. All nodes are clickable to reveal abstracts/links and to re-center the graph on that paper (building a new map).

Connected Papers also offers **Graph History** (company announcement). Additionally, Connected Papers can export results (e.g. to Zotero). Its interface is more static than ResearchRabbit's (no continuous updating streams), but users appreciate how **immediately understandable** the map is.

Strengths and Limitations: Aaron Tay (2021) notes that Connected Papers is *"easy to use and powerful"* for quickly finding semantically similar papers (aarontay.medium.com). Because it uses co-citation plus bibliographic coupling, it can find related work even for new papers with few citations (aarontay.medium.com). In practice, however, Connected Papers' free tier imposes small limits (about 5 maps per month) to encourage its paid plans (intranet.abertay.ac.uk). The biggest caveat is that, unlike full citation tools, edges in Connected Papers are *not actual citation links* (aarontay.medium.com). Thus one must interpret them as "these two papers share content." This is mentioned explicitly in its help: *"Connecting lines do not necessarily show direct citation relationships"* (aarontay.medium.com). Some users may find this confusing.

Connected Papers is best for an initial exploratory pass: putting in one well-chosen seed yields a map of ~50 papers that covers a broad neighborhood of the field. It's not designed for building a comprehensive review (it returns a fixed number of results). It also has no built-in alerting or timeline view. Its view is strictly one graph per query (multiple seeds require manual sequential updating).

User Perspectives: Research bloggers highlight Connected Papers' intuitive design. A review explains: *"Connected Papers takes a seed paper and generates a citation graph based on the seed, producing a visual network displaying how this paper is connected to others through direct citations and co-citations"* (academiainsider.com). It emphasizes discovering *"the most relevant papers... revealing the 'big picture' of research trends"* (academiainsider.com). Indeed, a researcher will quickly spot which papers in the graph have the most connections (large nodes) and which clusters cover subtopics. Dr. Andy Stapleton notes it is great for *"a one-shot visualization"* and can highlight seminal works. He warns that to go deeper, one must re-seed and re-run.

Inciteful

Overview: Inciteful (inciteful.xyz) targets users who want **advanced control** over literature networks. It allows importing not just a single seed but *multiple seeds* from the start (via batch BibTeX). With these, Inciteful constructs a comprehensive hall of related papers. Its default mode produces several curated lists (similar to

an advanced bibliography): *“Similar papers”* (papers co-cited with the seeds), *“Most Important Papers in the Graph”* (via PageRank algorithm), *“Recent papers by top authors”*, and more (aarontay.medium.com). These are displayed in an interactive web page rather than a force graph. Users can apply keyword or distance filters (e.g. exclude all papers beyond 3 citation “hops” from any seed) to narrow results (aarontay.medium.com).

Data & Methods: Inciteful acknowledges contributions from open scholarly data projects in its Data Sources documentation; it explores citation paths using standard graph algorithms (Adamic/Adar for similarity, PageRank for influence) (aarontay.medium.com). Crucially, Inciteful also exposes its queries: any list has a SQL button to show the actual database query used (aarontay.medium.com). Advanced users can tweak these SQL queries to customize the criteria for, say, “similar papers.” Behind the scenes, Inciteful’s architecture is more of a database layer than pure AI. It allows complex Boolean filters, including Porter stemming on keywords (aarontay.medium.com).

Features: A unique feature of Inciteful is *citation pathfinding*. Given two papers, Inciteful can show *how* one might be connected to the other through citation chains. This helps discover “bridge” papers that link two fields. Another highlight is the interactive graph view it provides: while the main usage is list-based, Inciteful also can show a visualization where all selected papers are nodes, and lines show citation links (with edge length proportional to citation distance). The SQL-editing feature is notable: users can manually adjust the algorithms (for example, to weight recent papers more heavily) by editing the queries behind the scenes (aarontay.medium.com).

Strengths and Limitations: Inciteful is very flexible for power users and small teams. It is free to use (no advertised paid tier). Unlike Connected Papers’ fixed number of nodes, Inciteful can suggest *hundreds* of papers if needed. It is best for deep dives on specific research questions, where you already have some starting papers and want to find connecting literature. The interface can be less intuitive for novices (many options and lists) but experienced users value the SQL transparency.

AI Research Assistants and Search Tools

Besides mapping platforms, a growing set of **AI assistants** aim to help with literature search and synthesis. These tools often combine multiple capabilities: searching across databases, filtering results, summarizing papers, and even draft writing. We examine several notable ones, especially **Elicit** and related tools, comparing how they integrate AI (especially language models) with literature data.

Elicit

Overview: Elicit (elicit.org) is a prominent AI assistant developed by Ought (formerly a nonprofit research lab) and now a public-benefit company. It is designed to automate parts of the systematic review workflow (www.researchgate.net) (bmcmedresmethodol.biomedcentral.com). Unlike pure mapping tools, Elicit does not primarily visualize citations; it answers specific research queries. Users enter a question (in natural language), and Elicit uses LLMs (initially GPT-3.5) plus specialized retrieval to find and synthesize relevant papers (bmcmedresmethodol.biomedcentral.com). Elicit primarily ranks papers by similarity in content or meaning rather than keyword frequency (Elicit Paper Search).

Features: Elicit’s capabilities include:

- **Semantic search:** It accepts a research question and retrieves papers semantically related (even if keywords differ) (bmcmedresmethodol.biomedcentral.com). This goes beyond Boolean keyword search. For example, in the BMC study, authors noted Elicit *"uses semantic similarity to identify papers relevant to a research question across multiple databases, even if those papers do not employ the exact keywords"* (bmcmedresmethodol.biomedcentral.com).
- **Summary generation:** For a given topic, Elicit auto-generates a summary report covering key aspects (definitions, arguments, methods, results, etc.) by analyzing the abstracts of retrieved papers (bmcmedresmethodol.biomedcentral.com). Its "Custom Experiment" feature can answer tailored queries and output synthesized answers.
- **Extraction of details:** Elicit can extract specific data (e.g. population, intervention) from papers and present them in tables, aiding evidence synthesis (bmcmedresmethodol.biomedcentral.com).
- **Filtering & workflows:** It allows filtering by year, source type (e.g. meta-analyses), and tracks the search process. Elicit keeps track of your query history and results lists, and can export references. It also supports collaboration via shared "projects" and notes.
- **Interactive Q&A:** Beyond retrieval, you can ask Elicit questions and get direct answers (citing papers). For instance, it might answer "Which ligand has been developed for this enzyme?" by showing relevant paper snippets.

Real use cases abound: a student might use Elicit to outline the literature in a new field (using summarization and question answering to identify key themes), while a systematic reviewer might use its screening mode to accelerate title/abstract triage (www.researchgate.net) (bmcmedresmethodol.biomedcentral.com). The interface is web-based with search bars and interactive tables.

Evaluation: How well does Elicit perform compared to traditional searches? Several studies give insight. Lau & Golder (2025) compared Elicit to published reviews and found mixed results (www.researchgate.net) (labs.sciety.org). In four case studies, Elicit's **sensitivity** (completeness) was only ~38–40%, far below the ~94% achieved by manual database searches (www.researchgate.net) (labs.sciety.org). In plain terms, Elicit missed over half the studies included in those reviews. However, its **precision** (relevance) was much higher: around 40% of Elicit results were ultimately included, compared to only ~8% from broad database sweep (www.researchgate.net) (labs.sciety.org). In other words, Elicit surfaced far fewer irrelevant hits. Moreover, each study noted Elicit found a few *new* studies that the original search had missed (www.researchgate.net) (labs.sciety.org).

Bernard et al. (2025) compared Elicit with an AI-independent umbrella-review search. Their abstract reports **three shared articles, three identified only by Elicit, and seventeen identified only by the AI-independent review** (study abstract). These are the abstract's reported counts.

Strengths & Limitations: Elicit is powerful for **rapid exploration**. It excels at quickly summarizing small sets of papers. According to user guides, it can condense a batch of papers (e.g. 8 most-relevant articles) into a structured synthesis (bmcmedresmethodol.biomedcentral.com). It also allows iterative querying ("show me more" until saturation). Its semantic search can uncover relevant papers missed by keyword queries. The DeepUseCase review highlights its features: automatic paper summarization, concept extraction, and an ability to answer free-form questions (deepusecase.com). Elicit even extracts data tables and supports population/intervention filtering (deepusecase.com) (bmcmedresmethodol.biomedcentral.com).

However, the aforementioned studies underline its limitations. Because Elicit retrieves only a finite set of papers (often dozens per query), it can miss many relevant studies, making it unsuited for exhaustive searches like clinical systematic reviews. Its effectiveness depends on the query formulation and filters chosen. Users must carefully apply broad queries and try multiple runs to capture enough literature. Additionally, all AI-based outputs must be validated manually for accuracy; Elicit can hallucinate or misinterpret, so final references and summaries need human checking (www.researchgate.net) (bmcmedresmethodol.biomedcentral.com).

In current form (2025), Elicit is best seen as a *literature triage assistant* – excellent for brainstorming directions, drafting screening criteria, and generating first-pass summaries. Journal article metrics suggest rapid adoption: one report claims over **500,000 registered users by mid-2025** (seosandwitch.com). According to Elicit's own blogs, it is integrated at many universities and has users in 130+ countries (seosandwitch.com). However, experts advise that Elicit and similar tools remain *adjuncts* rather than replacements for thorough search protocols (bmcmedresmethodol.biomedcentral.com) (labs.sciety.org).

Other AI Tools for Research

Beyond the above, a handful of other platforms are noteworthy:

- **SciSpace (Typeset's AI)**: SciSpace's ChatPDF provides explanations and answers while reading a research paper (SciSpace's introduction). It provides real-time reading aids (paper summaries, concept maps) using AI. SciSpace integrates with various databases and has over 10,000 journals indexed. It tends to be used more by students for extracting information from a single PDF, rather than broad mapping of citation networks.
- **Consensus.app**: Consensus describes itself as an AI workspace for scientific research (company information). Users enter a query, and Consensus returns an answer with cited snippets from papers. It's akin to a Q&A aggregator (similar to the now-defunct SciStack or scite.ai's assistant). Consensus does not build maps but is useful for quick factual answers gleaned from the literature. Because it uses pre-indexed content, it is typically global in scope (legal/econ/Education, etc.), but its depth varies by field. A Texas A&M guide lists Consensus under "AI search tools" for rapid academic Q&A (tamu.libguides.com).
- **Semantic Scholar**: Not a "tool" made by third-party developers in the AI sense, but Semantic Scholar itself is worth noting. It is an AI-powered search engine by the Allen Institute. It uses machine learning to surface papers, identify key topics, and show citation influence (TLDR for one paper, graphs of citation context, etc.). Semantic Scholar's Research Feeds recommend similar papers (product documentation). While not a mapping app, its built-in AI features (like influential citation extraction) complement those tools.
- **Iris.ai**: Iris.ai is an older platform (launched ~2016) that uses AI to classify papers by concepts. Given an abstract or paper, it can find related work and identify conceptual overlap. It was initially built on unsupervised ML (topic modeling and neural nets). Iris.ai's focus is on automation of the screening step: for example, a user can upload a seed paper and let Iris.ai find papers with overlapping concepts, returning a visual word map of topics. However, Iris.ai's adoption in academic circles is modest.

- **Scite and Similar Tools**: Scite.ai (not to be confused with Consensus) provides smart citations (percentages of supporting/contradicting citation statements). Its main mapping feature is the *Scite Assistant* browser extension or APIs, which can summarize a paper's claims or list key supporting citations. This helps in assessing credibility. While not a visual mapping tool per se, Scite's AI (and related "citation sentiment" tools) are increasingly integrated by researchers to quickly evaluate how a paper has been cited. These highlight that mapping is more than network graphs: modern tools also annotate **how** papers connect.

In summary, the AI tools for literature can be categorized roughly as:

1. **Visual mapping/exploration** (ResearchRabbit, Litmaps, Connected Papers, Inciteful, etc.), and
2. **Search & summarization assistants** (Elicit, Consensus, Iris.ai, SemanticScholar AI). Table 2 compares a few prominent examples from category (2) alongside Elicit for context.

Tool	Function	Unique AI Capabilities	Input / Interface	Freemium / Cost
Elicit	Literature discovery & synthesis	Uses GPT-based semantic search; auto-summarizes question results; "custom reports" (extracts PICO elements, tables) (bmcmedresmethodol.biomedcentral.com) (deepusecase.com). Supports iterative Q&A.	Query box (natural-language questions). Search results meta-data and summary panels.	Free basic; Pro/Team tiers with higher limits and features.
Consensus	Q&A via aggregated search	Returns answers drawn from multiple papers; cites sources. Uses ML to score relevance of papers to query.	Query box; returns paragraph answers with footnotes. Mobile-friendly.	Free (limited features), paid academic plan for full features.
SciSpace AI	Paper reading & Q&A	Reads PDFs; provides TLDR, browse-by-keyword/figure, automated math OCR. New "Article Q&A" uses OpenAI GPT-4 to answer questions about paper.	Upload PDF or browse known papers; interactive chat/Q&A interface.	Free tier; Pro ($11/mo) for advanced features.
Semantic Scholar	Academic search engine	AI ranking of papers; identifies keywords, influential citations, associated topics. Research Feeds recommend similar papers (product documentation).	Search bar or paper lookup; displays AI highlights (key phrases, TLDR) and citation flows.	Completely free (funded by non-profit).
Iris.ai	Paper screening & mapping	Builds "AI research maps" via unsupervised concept extraction; topic clustering of uploaded papers.	Upload PDF or abstract as "seed"; shows concept map of related papers.	Freemium; limited daily usage on free plan.

Table 2: Selected AI-based literature search/synthesis tools. These tools often overlap in function. Elicit's approach is to guide a review question through successive AI-driven search and summarization steps (with study after study added to its analysis). In contrast, Consensus is a lightweight engine to get quick factual answers. Semantic Scholar doesn't map papers visually but uses AI to highlight key nuggets from any single paper. A Texas A&M libguide notes that tools like these are *"fast-moving and highly volatile"* as of 2025 (wiki.ubc.ca) – new players emerge (e.g. "Luzia", "Poe") while services update frequently.

Data and Performance Analysis

A critical aspect of evaluating these tools is empirical performance. Several recent studies have compared AI tools to traditional methods:

- **Elicit vs Traditional Search:** Lau & Golder (2025) and Bernard et al. (2025) provide quantitative comparisons of Elicit's search versus manual review. The key metrics were *sensitivity* (how many of the relevant papers were found) and *precision* (what fraction of found papers were actually relevant). Both studies found Elicit's sensitivity to be far lower. Lau & Golder report Elicit averaged **39.5% sensitivity** (i.e. it found roughly 40% of the known relevant studies), compared to about 94.5% for the original systematic searches (www.researchgate.net). Bernard et al. similarly found only **17.6% overlap** with the classical method in one case (bmcmedresmethodol.biomedcentral.com). In exchange, Elicit's precision was much higher: Lau & Golder found ~41.8% precision for Elicit vs ~7.6% for the original reviews (www.researchgate.net). This means Elicit returns a shorter, cleaner list of likely relevant papers, but misses the majority. Importantly, each study noted Elicit also contributed unique findings: a few papers were found by Elicit that classic searches missed (www.researchgate.net) (bmcmedresmethodol.biomedcentral.com). The consensus conclusion is that Elicit (and by extension similar tools) can be a *useful adjunct* – they can speed up screening, prune irrelevant hits, and even uncover missed references (www.researchgate.net) (bmcmedresmethodol.biomedcentral.com) – but they are **not sensitive enough** to rely on for exhaustive searches (bmcmedresmethodol.biomedcentral.com) (labs.sciety.org).
- **User Experience & Time Savings:** Anecdotal evidence strongly supports that these AI tools save time. For example, one academic blogger reports that tasks she used to spend three weeks on now take only a few days with tools like ResearchRabbit and Elicit (techpoint.africa). Librarians have started recommending them as scoping tools. A survey by DeepUseCase (2024) notes that the main reported benefit is improved **time management**: researchers spend less time on tedious searching and can move faster to analysis (techpoint.africa). We found few large-scale user data from published literature, but company reports suggest rapid uptake (e.g. Elicit's claimed 500k users (seosandwitch.com); however, these are not independently verified).
- **Coverage and Bias:** As noted, all tools rely on the underlying database. We cite Abertay University's advice: *"These tools may miss paywalled content. Many summarise based on abstracts, not full text. They work better in some fields (STEM, medicine) than others (humanities). Book coverage is especially weak."* (intranet.abertay.ac.uk). This is crucial: AI mapping tools are only as good as their input data. For example, a user in legal research found most legal journals absent, whereas a neuroscientist found excellent coverage in PubMed-sourced tools. Thus, researchers must know the scope of each tool's dataset.
- **Reproducibility:** Another key issue is reproducibility. The Abertay guide warns that these AI tools are *not fully reproducible* (intranet.abertay.ac.uk). Two users might get different suggestions for the same seed, because the algorithms and indexed data change over time. In systematic reviews, lack of

reproducibility is a red flag. Unless the tool can be locked to a date and query history, one cannot guarantee the same results if rerun. **Best practice**: if using these tools, carefully record the seed inputs and date, and only use them for exploratory scoping rather than definitive evidence gathering.

- **Bibliometric Accuracy:** The graphical maps themselves can introduce bias. For instance, Aaron Tay notes that Connected Papers' similarity graph is *"not necessarily showing citation relationships"* (aarontay.medium.com). This can mislead if interpreted incorrectly as actual citation flow. Also, tools may overweight highly-cited papers (as seen by node size) even if those are "review" articles or out-of-scope. Users must filter and judge relevance carefully.

Case Studies and Examples

Documented evaluation example: Elicit reports using BioASQ to compare its semantic search API with commercial and academic search APIs (Elicit's evaluation). This is a provider-reported evaluation.

Discussion and Future Directions

The proliferation of AI tools for literature mapping and review has profound implications. **On the positive side**, these tools democratize advanced discovery. Individual researchers and small teams can access capabilities (visual mapping, semantic search) that once required specialized skills. Time savings are substantial: what used to take months can be done in weeks or days (techpoint.africa). There is also more transparency: many tools allow exporting data, so a researcher can easily incorporate recommendations into a formal methodology (e.g. export a set of seed citations to Zotero or CSV). Tools like Inciteful even let you see and tweak the SQL queries underpinning the recommendations (aarontay.medium.com), adding a layer of reproducibility for those who look under the hood.

Challenges and biases remain. The reliance on open metadata means that research from humanities, non-English publishers, or closed-access journals can be underrepresented (intranet.abertay.ac.uk). The algorithms often reinforce existing citation biases (popular papers get highlighted, interdisciplinary work falls into gaps). As noted, the AI-generated maps are not static truth but tools requiring critical judgment. Another concern is *overreliance*: if early-career researchers take these tools as authoritative, they might systematically miss important work not surfaced by AI. For example, a classical paragraph in librarian guides cautions that these tools *"should not replace formal literature review methods"* (intranet.abertay.ac.uk). Scholars must still carefully read and evaluate articles; the tools only suggest leads.

Looking ahead, several trends emerge:

- **Integration with Generative AI:** Many mapping tools are beginning to add LLM features. For example, Scite's citation maps now have a GPT-powered assistant to answer questions about a cluster. We expect future versions of Litmaps or RRabbit to include automated summarization capabilities (e.g. GPT-4 summarizing a node). Elicit itself is evolving: its 2025 release announced an "Elicit Systematic Review" workflow that more tightly integrates screening and data extraction (elicit.com). The fusion of

knowledge graphs with LLMs (e.g. Retrieval-Augmented Generation systems) promises more powerful search: imagine asking “what are the main unsolved problems in X?” and getting a map, summary, and list of cluster papers in one go.

- **Improved Data Coverage:** OpenAlex is an open scientific knowledge graph launched to replace the discontinued Microsoft Academic Graph (OpenAlex’s developers). As more publishers release open metadata, tools can index larger swaths. Tools like Litmaps already ingest OpenAlex data (docs.litmaps.com). We may see partnerships: e.g., Scopus or Web of Science opening APIs to AI tools for certain queries. For maximum benefit, the research community will need to advocate for open citation data.
- **Standardization and Reproducibility:** There is a push to make AI-assisted reviews more transparent. The Cochrane Equity Methods Group, for example, is investigating guidelines for using tools like Elicit in evidence synthesis. We anticipate **best practice frameworks** that specify how to record AI tool queries (seed papers, date, algorithms used) when using them in systematic searches. This may involve integration into PRISMA reporting. Some tools are already adding logs or “history” exports.
- **Social and Ethical Issues:** As these tools embed into research, questions arise: who gets credit for discoveries made via AI recommendations? If an overlooked paper found by AI later becomes central, is the AI a co-discoverer? Researchers should critically track provenance. Data privacy is another concern: uploading unpublished manuscripts or sensitive content into third-party AI tools could violate ethics. Library guides explicitly warn against this (intranet.abertay.ac.uk).
- **New Mapping Paradigms:** Future research tasks may require more than citation graphs. For example, tasks like *literature-based discovery* (finding hidden cross-domain links) could leverage knowledge graphs plus AI reasoning. We may see new tools that integrate alternatives sources: e.g. merging patent databases, social media (tweet mentions), or even funding data into the map. The concept of a “meta-map” could emerge (map of fields, with AI highlighting where fields intersect).

Overall, the trajectory is clear: AI will continue to augment how we navigate research. While no single tool is perfect, the ensemble of literature maps, semantic search, and generative summarization is reshaping scholarly discovery. Researchers and educators must stay informed about these evolving tools. Just as Google Scholar revolutionized search in 2004, the AI mapping assistants of 2025-30 may become ubiquitous academic companions. But as with any powerful tool, scrutiny and methodological rigor remain vital.

Conclusion

The landscape of scientific literature is too vast for any human to fully survey unaided. The recent wave of AI-based literature tools offers powerful means to “map” this landscape. Platforms like ResearchRabbit, Litmaps, Connected Papers, and Inciteful create rich visual networks of papers that help researchers see connections at a glance (intranet.abertay.ac.uk) (aarontay.medium.com). Meanwhile, assistants like Elicit leverage language models to crawl literature quickly and compile summaries (bmcmedresmethodol.biomedcentral.com) (labs.sciety.org). Our review has shown that each tool has its niche: some excel at exploratory navigation,

others at data extraction. Empirical studies confirm that AI tools can greatly reduce the workload of literature reviews, though they do not yet match human thoroughness (www.researchgate.net) (bmcmedresmethodol.biomedcentral.com).

For AI researchers and scientists, these tools can dramatically speed up staying current with the literature and finding interdisciplinary connections. For example, one can discover links between AI subfields by visualizing citation overlaps; or rapidly gather all papers on a new neural architecture via semantic search. As one user observed, AI mapping “lets you stay updated on changing literature” (docs.litmaps.com). In teaching, these tools offer new ways to train students in research methodology.

Looking ahead, the synergy of these tools with larger AI systems is promising. In the near future, a researcher might ask a tool to “map the state of the art in federated learning” and get back both a styled network graph and a synthesized summary. Our analysis indicates the technology is maturing: user base numbers are rising (seosandwitch.com), and research on these tools (like LitLLM’s new retrieval-augmented approach (arxiv.org)) continues at top AI institutes.

In sum, Literature mapping tools for AI-assisted research are transitioning from niche gadgets to staples of the scholarly toolkit. They enable deeper insights by literally *visualizing* knowledge. As these systems improve, they could transform how scientists assess “who said what” across vast literatures, accelerating innovation. However, the community must remain vigilant about their limitations, ensure transparency, and use them alongside (not instead of) critical human scholarship.

THE PUBLISHER

About IntuitionLabs

IntuitionLabs is an AI consulting, custom software development and data engineering firm serving pharmaceutical, biotechnology, medical-device and other life-science organizations. We work with clinical, regulatory, medical-affairs, commercial, quality and IT teams to connect technology decisions with the work people need to accomplish.

AI consulting and adoption

Our AI enablement services cover readiness assessments, use-case selection, governance and policies, team workshops, adoption measurement and ongoing advisory support. We help organizations structure the information layer behind AI: source material, context, permissions and maintained knowledge that make generated answers useful and reviewable. Private LLM inference and hosted AI options support teams evaluating how to operate AI with appropriate control over their data and infrastructure.

Software, data and life-science workflows

IntuitionLabs develops custom software for pharma and biotech, integrates enterprise systems, and builds data engineering and business intelligence solutions. Areas of focus include AI agents, regulatory research, medical writing, medical affairs, CMC information, competitive intelligence and clinical-document workflows. Our eTMF intelligence work includes cross-system reconciliation and inspection-readiness support.

Enterprise platforms and regulated delivery

We provide Veeva services, application support, managed services, integrations and custom applications, alongside enterprise content work involving platforms such as Egnyte. For regulated workflows, our services include GxP enablement, computer-system validation and software development addressing 21 CFR Part 11 requirements. The applicable controls, validation responsibilities and acceptance criteria are defined for each engagement.

Work with IntuitionLabs

Explore AI enablement, pharma and biotech software development, data engineering and BI, and Veeva services. Contact IntuitionLabs to discuss your workflow, information sources and implementation needs.

IntuitionLabs publishes educational research to help life-science teams make informed technology decisions. Coverage of a product or organization does not imply a client relationship, endorsement or partnership.
